

We Claim:

1. A blood processing system communicating with a blood separation device comprising

first and second fluid pressure actuated pump stations, and

5 a fluid pressure actuator operating to selectively apply fluid pressure pump strokes in tandem to the first and second pump stations to convey fluid from a source to a destination, the fluid pressure actuator including a control function to switch between
10 a first flow mode, in which the pump strokes draw a fluid volume into the first pump station from the source and expel a fluid volume from the second pump station to the destination, and a second flow mode, in which the pump strokes draw a fluid volume into the second pump station
15 from the source and expel a fluid volume from the first pump station to the destination, the control function operating to synchronize the pump strokes so that fluid flow from the source is essentially continuous while fluid flow to the destination is pulsatile.
